CHAMPION

The right plug for your bike

Figure 1

The Selection

When selecting a plug for a motorcycle recommendation, besides the obvious characteristics such as physical size, we at Champions have to consider the appropriate heat range for your motorcycle. Too hot a type and a piston is holed, too cold a type and the plug fouls although doing no damage to the engine. Let's face it though, it's never convenient to breakdown.

So for optimum performance we test and select our recommendations using a special thermocouple plug, that is a plug with an electronic thermometer attachment in effect, this then determines the correct heat range for an application.

What Is Heat Range?

A plug's heat range described clinically is a plug's ability to dissipate heat from the core nose under varying conditions. To explain this a little more simply however, a basic appreciation of a plug's design is in order. In the illustration (fig. 1) you will see how the ceramic section of the plug, the insulator, seats on a ridge in the steel part or shell. From the seating downwards is the core nose, the length of which effectively determines the heat range. Ceramic being a poor conductor of heat allows Champion Engineers to 'tune' a plug to suit an engine by trying various core nose lengths: The longer the core nose, the longer the heat takes to travel up to the seat within the shell from where it dissipates into the cylinder head as shown.

The main consideration for combustion chamber heat is the compression ratio, higher compression means higher temperatures. Taking these two previous statements into account, we now have to consider that a plug has its own working parameters, a lower temperature of about 400°C and an upper temperature of 850°C. Below 400°C and deposits accumulate from the combustion process, above 850°C the electrode erosion increases dramatically and above 900°C pre-ignition occurs with the final result being damage to both plug and piston.

Therefore, the heat range of a plug is basically determined by the core nose length.

Variety Is The Spice(1)

Variety of core nose configuration can be the spice of longer plug life! Champion Engineers developed the projected core nose plug back in the 1930's (figs. 2/3) and they are probably the most common plug design in use today, although only recently have they become popular in the motorcycle market.

The principle is that a longer core nose projects down into the combustion chamber, at low engine speeds; this acts like a conventional long core nose or hot type spark plug and dissipates heat slowly. In keeping with hotter plug types any deposits are burned off. As engine speed increases however, the 'breathing' or gas flow into the combustion chamber improves allowing the cooler incoming gases to cool the core nose portion that extends into the combustion chamber, thus artificially reducing the heat to be dissipated into the engine's cooling system (figs. 5/6). The projected core nose type therefore offers better protection against fouling and pre-ignition than a conventional firing end.

Variety Is The Spice(2)

Gold Palladium plugs were developed on principles established using our aero industry experience. This design features a fine wire electrode (see fig. 4) allowing a smaller gap to be run than with conventional types, as the spark masking effect is considerably reduced, thus aiding easier starting and eliminating the misfire often associated with small spark gaps. The longer, slimmer core nose provides a greater shunt path distance to earth, in addition to a greater cavity volume between the core nose and plug shell allowing more efficient gas scavenging.

The Gold Palladium plug therefore offers easier starting, better protection against fouling and its effects and usually a longer service life.
